Abstract—Discrete Event System Specification (DEVS) is a modular and hierarchical formalism for system modeling and simulation. DEVS models can be mathematically described; simulation is performed by tools called concrete simulators. Concerning atomic DEVS models, each concrete simulator has its own input language which is, essentially, a general-purpose programming language (such as Java or C++). Hence, once engineers have written the mathematical model, they need to manually translate it into the input language of the concrete simulator of their choice.

In this paper we present a multi-target compiler for atomic DEVS models written in CML-DEVS, a mathematics-based DEVS modeling language. This multi-target compiler is able to compile a CML-DEVS model to the input languages of the PowerDEVS and DEVS-Suite concrete simulators. In this way, the CML-DEVS compiler frees engineers from the manual translation of their mathematical models. In fact, the same mathematical model can be simulated on both simulators by simply re-compiling the model. The CML-DEVS multi-target compiler can be easily extended to produce code for other concrete simulators.

Index Terms—DEVS, atomic model, CML-DEVS, compiler

I. INTRODUCTION

Discrete Event System Specification (DEVS) [1] is perhaps the most general and used modeling and simulation (M&S) formalism. When using DEVS, a system is modeled by giving its structure, through a coupled DEVS model, and its behavior, through one or more atomic DEVS models, which are composed in intermediate coupled models that at some point form the final coupled model. Simulation of these models is performed by tools called concrete simulators (for instance, DEVS-C++ [2], DEVSim++ [3], CD++ [4], PowerDEVS [5], JDEVS [6], DEVS-Suite [7], LSIS-DME [8]). Usually a concrete simulator provides to its users: a) a way to compose atomic or coupled models into coupled models; and b) a programming language to program atomic models, which in general is the same programming language of the concrete simulator.

Giving the structure of a coupled DEVS model is rather easy as tools frequently rest on some sophisticated graphical user interface (GUI) that allows engineers to graphically compose their atomic and coupled models. Indeed, these tools let engineers not in the habit of programing, to compose their models as they learned in textbooks. They also learned that DEVS atomic models should be described in the standard language of mathematics by using equations, functions, sets, etc. However, when they want to simulate these atomic models they need to program them in the input language of a concrete simulator, which means to write code in Java or C++ or other general-purpose programming language. Or else, they need to ask a programmer to do that. Furthermore, if they want to experiment with different concrete simulators they need to re-implement their models for each of them. The process of translating the mathematical model to the input language of a concrete simulator, may induce errors that would render the simulation activity not as accurate as it should be.

For these reasons, we developed CML-DEVS [9], a DEVS specification language based on standard mathematics and inspired in formal notations such as Z [10], B [11] and TLA+ [12], which are used by the Software Engineering community. CML-DEVS models may be used to abstractly describe DEVS atomic models, which can later be composed as done by each concrete simulator. In the context of CML-DEVS, abstract model and CML-DEVS specification denote a model described in the language of mathematics and logic. One of the objectives we had in mind when designing CML-DEVS was that it should be possible to automatically translate any CML-DEVS model into the input languages of the main concrete simulators.

In this paper we present a multi-target compiler for CML-DEVS models. That is, we present a program that reads a CML-DEVS specification and generates a program in the input language of a concrete DEVS simulator. In turn, this program generated by the CML-DEVS compiler can be compiled as indicated by the concrete simulator in order to simulate it. Therefore, the combination of CML-DEVS plus its multi-target compiler relief engineers from the error-prone, difficult task of translating their abstract models into concrete models. CML-DEVS plus its multi-target compiler let engineers to think in terms of mathematics and to use several different concrete simulators for simulating the same model.

In this first version the compiler produces PowerDEVS [5] and DEVS-Suite [13] code, that is, essentially, C++ and Java code, respectively. However, we show how it can be extended to produce concrete models for other tools. In effect, by following standard compiler design techniques, our CML-DEVS compiler provides the functionality for parsing, type checking, AST construction, etc. of CML-DEVS code in such a way that producing object code for different concrete simulators is a rather easy task. The tool presented in this paper is a proof-of-concept, not a production tool. As such, it can be improved in many ways although it features the basic structure and functionality of more advanced tools. With this tool we aim at showing to the DEVS community an
alternative, complementary technology for modeling atomic DEVS models. In spite of this, we encourage the DEVS community to experiment with the current version of the compiler as it provides a new way of writing DEVS atomic models.

The CML-DEVS compiler can be freely downloaded, modified and extended; it can be found here http://www.cfasis-conicet.gov.ar/hollmann/projects/CML-DEVS.

The paper is structured as follows. In Section II we introduce, by means of a class-room example, the CML-DEVS specification language, assuming the reader is familiar with DEVS (otherwise refer to [1]). The CML-DEVS multi-target compiler is described in Section III where we comment on key design decisions that guided us towards its implementation. An empirical evaluation of the compiler is presented in Section IV. This evaluation consists in collecting fourteen atomic DEVS models, writing them in CML-DEVS and compiling them to PowerDEVS and DEVS-Suite input languages with the CML-DEVS compiler. Integration of the CML-DEVS approach with existing DEVS tools is discussed in Section V. Similar and related works are described in Section VI. Finally, we give our conclusions in Section VII. The Appendix contains further technical information referenced throughout the paper.

II. INTRODUCTION TO CML-DEVS

CML-DEVS has been discussed in detail elsewhere [9]. Here we will show its main features by means of an example. We want to focus on the fact that writing CML-DEVS code is equivalent to what software engineers do when writing formal specifications in formal notations such as B [11]. In other words, we claim that CML-DEVS captures the mathematics used to write atomic models as in DEVS textbooks or as in the classroom in such a manner that tools can be built to process this language. Another analogy that might apply is that CML-DEVS is to DEVS what L\textsc{\textit{A}}\textsc{\textit{T}}\textsc{\textit{E}}\textsc{\textit{X}} is to mathematics. In this sense, mathematicians do not find writing math formulas with L\textsc{\textit{A}}\textsc{\textit{T}}\textsc{\textit{E}}\textsc{\textit{X}} particularly annoying although it requires some learning process.

Therefore, Figure 1 shows an atomic DEVS model written as in DEVS textbooks or in DEVS courses (e.g. [1], [14], [15], [16], [13], [17], [18], [19], [20]) while Figure 2 shows a pretty-printing of the CML-DEVS source code shown in Figure 3 corresponding to the model of Figure 1. What the model in Figure 1 represents is, at this point, not really important. Instead, we want to emphasize the fact that Figure 1 is a mathematical, abstract, simulator-independent description of a DEVS atomic model. In other words, we claim that people in the DEVS community would agree in that Figure 1 represents a typical textbook or classroom description of a DEVS atomic model.

In turn, note that Figure 2 is, essentially, a mathematical formula much like the one shown in Figure 1. It rests on equations, functions and set theory, with no influence whatsoever from a general-purpose programming language.

On the other hand, the CML-DEVS source code of Figure 3 is aligned with the way specifications in formal notations such as Z, B and TLA+ are written. We think the code is self-explanatory and respects the way engineers write their abstract models. Besides, consider the following observations:

1) CML-DEVS is based on logic, set theory, equations and function definitions;
2) There are no side effects as it is a declarative language enjoying referential transparency [21];
3) This source code can be generated by, for example, a formula editor featuring a rich graphical user interface;
4) Pretty-printing (Figure 2) could be done by a simple translation tool producing L\textsc{\textit{A}}\textsc{\textit{T}}\textsc{\textit{E}}\textsc{\textit{X}} or XML code; and
5) It is independent of any concrete DEVS simulator, relieving users from learning several programming languages.
III. The Design of the Multi-Target CML-DEVS Compiler

In this section we describe the main features and design of the CML-DEVS multi-target compiler (or compiler for short). The description is somewhat detailed as we intend it to help the DEVS community to either implement similar tools or improve the one described in this paper. Some of the design decisions we show here were made for quickly providing a working tool for the DEVS community. In Section III-B we discuss the pros and cons of the present approach.

The CML-DEVS compiler is a Java program based on a standard one-pass compiler design and on the ANTLR parser generator [22]. Figure 4 shows a descriptive block diagram of the structure of the compiler. It is multi-target as it is conceived to generate code for different concrete simulators from the same CML-DEVS model, as we explain in Section III-A. In this first version, though, it generates only PowerDEVS [5] and DEVSSuite [13] [7] code which are essentially C++ and Java code, respectively. As we have said, this tool is a proof-of-concept whose main goal is to demonstrate the feasibility of the CML-DEVS approach. Then, we believe that the “multi-target” feature is demonstrated by generating code for more than one simulator and by showing that each new code generator can be easily implemented (see Section III-A). Today the CML-DEVS compiler is less than 20 KLOC including comments (15 KLOC of pure Java code).

The CML-DEVS grammar informed in [9] was written in the grammar language supported by ANTLR. In this way, ANTLR generated the lexical analyzer (scanner) and the syntax and semantic analyzer (parser). These two functional components are implemented by a collection of Java classes automatically generated by ANTLR. The main function of the parser is to generate an abstract syntax tree (AST) of the CML-DEVS model. This AST is a central data structure as it organizes the model being compiled as a tree structure. The AST has a node for each terminal and non-terminal defined in the grammar that is being used in the model, where its children are the tokens that build it. For example, in the CML-DEVS code of Figure 3, ta is represented as a node whose only child is the defcases structure who, in turn, has four children, one for each case sentence. Hence, there is a Java class for each token defined in the grammar. However, these classes provide only syntactic information. ANTLR organizes these classes according to the Composite design pattern [23, ch. 4–Composite], which allows a uniform access to the structure. In particular, an object structure adhering to a Composite can be analyzed by implementing the Visitor design pattern [23, ch. 5–Visitor]. This combination of design patterns facilitates the implementation of several key functions of the compiler.

Attempting to generate target (object) code from this AST is quite complex as the AST does not contain semantic information—for instance, it is not possible to know the type of each expression. For this reason, as shown in Figure 4, we decided to augment the AST with semantic information. In this way code generation (Section III-A) becomes simpler.

Besides, ANTLR automatically generates a template visitor interface (CMLDEVSVisitor) specifically tailored to analyze the AST generated during the parsing phase (see Figure 15 in the Appendix). Currently, the CML-DEVS compiler implements this interface with a set of classes headed by CMLDEVSVBaseVisitor whose function is to generate another AST containing semantic information about the model (i.e. the augmented AST). The heirs of CMLDEVSVBaseVisitor create the nodes of the augmented AST. In this way, it can be said that the implementation of CMLDEVSVBaseVisitor represents the intermediate code generator.

The AST generated by CMLDEVSVBaseVisitor is organized as a Composite design pattern headed by the CMLDEVSData interface (see Figure 16 in the Appendix). Each node in the augmented AST is a heir of CMLDEVSData containing information such as the semantic role played by each syntax element and the type of expressions. For example, in the augmented AST the ta node of the AST mentioned above, contains information indicating what is the definition part and the condition part of each case sentence, what is the

That is, an interface or a class parametrized by a type.
type of each variable participating in them, etc. This semantic information is stored in the heirs of CMLDEVSData. In this way, it can be said that the augmented AST is an intermediate language.

A. Code generation

Carefully designing the code generation phase (cf. Figure 4) is important in the CML-DEVS compiler as we intend it to be a multi-target compiler. The main design decision is to postpone code generation as much as possible. In this way, code generators do not need to implement other functions as they are provided by previous phases. Then, new code generators are small and simple and easy to add.

When calling the CML-DEVS compiler users must pass a parameter telling to what simulator language the compilation has to be done. This parameter is used internally to instantiate the proper code generator. In the CML-DEVS compiler, each code generator has three main responsibilities:

- Produce object code respecting the syntax and conventions of each concrete simulator;
- Distribute the final code in files according to the requirements set by each concrete simulator. For example, PowerDEVS requires three files for an atomic model (ModelName.pds, ModelName.h and ModelName.cpp), while DEVS-Suite [13], [7] requires only one (ModelName.java); and
- Substitute reserved words of the target language used in the CML-DEVS specification. For example, class is a reserved word in C++, Java, etc. but is not in CML-DEVS. Then, engineers may use class in their CML-DEVS specifications as a name for variables, constants, etc. but when the compiler generates code for a concrete simulator whose input language is based on an object oriented language, this word must be replaced because otherwise the generated model will not compile. We discarded the possibility to reserve more words at the CML-DEVS level because this would mean to collect the reserved words of all possible input languages of concrete simulators.

Each of these responsibilities is assigned to different classes, which have to be carefully created as they are related to each other. Creating families of related objects is the purpose of the Abstract Factory design pattern [23, ch. 3–Abstract Factory]. Hence, the CML-DEVS compiler defines TargetLanguageFactory, an interface for instantiating objects that depend on the target language (see Figure 17 in the Appendix).

Target code generation (i.e. the first responsibility listed above) is organized according to the Visitor design pattern [23, ch. 5–Visitor]. This visitor visits the Composite that structures the augmented AST headed by CMLDEVSData and print the final code. Hence, the CML-DEVS compiler defines the Printer interface such that each of its implementations will print object code corresponding to each sentence of the intermediate language. An excerpt of Printer’s interface is shown in Figure 5. Note that there are methods to print each terminal and non-terminal of the intermediate language. In this sense, the classes implementing this interface are known as pretty-printers or printers. In fact, these printers use StringTemplate technology to produce the final code. StringTemplate is a Java template engine for generating source code developed by ANTLR’s designer [24].

Therefore, implementing the code generator for PowerDEVS (respect. DEVS-Suite) implies to provide, among others, a heir of TargetLanguageFactory, called PowerDEV-
Suite code generators is about 1 KLOC, each. This shows that
generation, thus allowing a rapid prototyping of the compiler.
was chosen because it is one of the simplest forms of code
improved in the future by tool developers. This technique
in terms of performance, this technique can be changed or
can be used as the base to implement new ones.
the compiler but also by the fact that existing code generators
PowerDEVS. This means that the effort of implementing a new
implementation of three methods of PrinterPowerDEVS, and
Figure 7 shows an excerpt of the template. As can be seen,
the template consists in the basic structure of the code to be
generated with place holders that are replaced each time the
template is used. The replacement can be done with a library
provided by StringTemplate. The place holders are replaced
with the actual data taken from the augmented AST. For ex-
ample, in the second sentence of print(), in Figure 6, stHeader
is the instantiation of the template shown in Figure 7. Then,
this sentence replaces parameter $S$ of headerFile with the
result of print(atomic.getState()). whose implementation can
also be seen in Figure 6.

Hence, implementing a new code generator entails repeating
the implementation schema followed for the implementation
of the PowerDEVS and DEVS-Suite code generators. That is,
defining a heir of TargetLanguageFactory and an implementa-
tion of Printer and implementing it using StringTemplate.
That is, it would be convenient (although not mandatory)
to define a new template considering the peculiarities of the
input language of the concrete simulator. As a matter of fact,
the implementation of the methods shown in Figure 5 for
the DEVS-Suite simulator are almost identical to those of
PowerDEVS. This means that the effort of implementing a new
code generator is alleviated not only by the general design of
the compiler but also by the fact that existing code generators
can be used as the base to implement new ones.

Given that creating object code by printing can be bad
in terms of performance, this technique can be changed or
improved in the future by tool developers. This technique
was chosen because it is one of the simplest forms of code
generation, thus allowing a rapid prototyping of the compiler.
The code corresponding to the PowerDEVS and DEVS-
Suite code generators is about 1 KLOC, each. This shows that
the effort of implementing new code generators (cf. Figure
4) is marginal with respect to the total effort (recall that
currently the CML-DEVS compiler is about 20 KLOC), as
it is otherwise expected if proved compiler techniques are
followed. In turn, this suggests that the idea of defining a
specification language for atomic DEVS models and designing
a multi-target compiler for it, was right.

B. Discussion

In this section we discuss the advantages and disadvantages
of using the CML-DEVS approach (i.e. the CML-DEVS
language plus its multi-target compiler). CML-DEVS provides
a mathematics-oriented specification language for describing
atomic DEVS models. This is aligned with the way DEVS
models are presented in courses and textbooks. Instead, using
a general-purpose programming language demands engineers
not only to be experts in the problem domain but also
programmers. The CML-DEVS compiler complements the
specification language by generating code for (potentially)
many concrete simulators. This allows engineers to write an
abstract model once while being able to simulate it on many
different simulators. CML-DEVS is expressive enough as to
specify all of DEVS atomic models [9].

However, the approach is not exempt of limitations and
disadvantages. Engineers need to learn a new language (i.e.
CML-DEVS). This can be reduced to a minimum if a formula
editor is implemented. Nevertheless, either engineers learn
CML-DEVS or they learn to program in the input language of
a concrete simulator—in turn this is some times not the case
because engineers already know how to program. Learning
CML-DEVS has the advantage that they can use different
concrete simulators for free. The code generated by the CML-
DEVS compiler may be inefficient compared to the code
programmed by an expert on a particular concrete simulator.
Another issue with our approach is that changes in the design
of a concrete simulator (e.g. its input language) might imply
changes in the CML-DEVS compiler. However, the design
of the compiler would limit these modifications to specific
modules (in general to the code generation modules).

```java
public interface Printer {
    String print(State s);
    String print(DeltaInt dint);
    String print(TimeAdvance t);
    String print(Assignment assig);
    String print(Cases cases);
    String print(ListExpression listExpression , CMLDEVSType type);
    String print(NumberSetExpression numberSetExpression , CMLDEVSType type);
    String print(TextValue textValue , CMLDEVSType type);
    String print(Comparison Eq comparisonEq);
    String print(Operation Plus operationPlus , CMLDEVSType type);
    String print(Operation Mult operationMult , CMLDEVSType type);
    String print(Operation Mult operationMult , CMLDEVSType type);
    ...
}
```

Fig. 5. Part of Printer’s interface.
IV. EMPIRICAL EVALUATION

In this section we present the results of an empirical evaluation of the CML-DEVS compiler. The empirical evaluation aims at showing that:  

a) mathematically described atomic DEVS models can be written in CML-DEVS by just adhering to its syntax conventions;  
b) the compiler can produce concrete models for PowerDEVS and DEVS-Suite from the same CML-DEVS model;  
c) the resulting concrete models are syntactically more complex than the CML-DEVS models; and  
d) compilation times are reasonable.

The results of this empirical evaluation are summarized in Table I; Table II in the Appendix gives a brief informal description of each atomic model.

In Table I column T indicates whether the CML-DEVS specification was written from a mathematical description (D) or from the source code of an atomic PowerDEVS (C) or DEVS-Suite (J) model. Hence, as can be seen from the table, we collected a sample of 10 mathematically described atomic DEVS models plus 4 concrete models (ConstGen, HInt, BinaryCounter and Generator). All the 14 models were taken from third-party resources such as books, web sites and courses covering a wide range of applications, origins and authors, thus representing a reasonable sample—that is, these models were not proposed by us which would have biased the evaluation. In effect, we have collected models from six different sources and authorships. The sources include Cellier and Kofman’s book on continuous system simulation; the PowerDEVS library of atomic models; Professor Vangheluwe’s class notes of his course “Modelling of Software-Intensive Systems” given at McGill University; Professor Wainer’s repository on CD++ models which includes models written by students who took his courses “Simulation of Discrete Event Systems” given at Buenos Aires University and “Methodological aspects of modeling and simulation” taught at Carleton University; the technical report from Zeigler and Sarjoughian on M&S describing DEVS-Suite; and a model described by Professor Wainer himself in one of his class presentations. That is, there are models written by experts and students as well. Next, we have translated the models from the mathematical descriptions used by their authors into CML-DEVS specifications; and in the case of the 4 concrete models we wrote their CML-DEVS specifications from informal descriptions. In doing so we tried to follow the mathematical structure suggested by each author. We believe this supports claim a) mentioned above. That is, atomic DEVS models can be easily written in CML-DEVS.

Then, we used the CML-DEVS compiler to compile to PowerDEVS and DEVS-Suite each of the 14 DEVS atomic models. The concrete models produced by the CML-DEVS compiler can be simulated by the corresponding concrete simulator. In particular, models ConstGen, HInt, BinaryCounter and Generator allow us to compare the code generated by the CML-DEVS compiler with respect to the code written by PowerDEVS and DEVS-Suite expert users. In order to
keep the presentation concise, we include here the analysis of model HInt but similar conclusions can be drawn from the other three models. Model HInt is an hysteretic quantized integrator which is used in continuous system simulation, as defined by Cellier and Kofman [18]. Figure 8 lists the PowerDEVS code of HInt as proposed by Cellier and Kofman [18, p. 545]. In turn, the CML-DEVS code is in Figure 10 and the result of compiling it is in Figure 9. As can be seen, both PowerDEVS programs are similar in size, structure and functionality. Furthermore, in Figure 11 we can see the results of using both implementations (i.e. Figures 8 and 9) as part of a PowerDEVS simulation. It is obvious that both programs yield the same results, which is an indication that the compilation of the CML-DEVS specification behaves the same with respect to the original model.

Given that all the 14 CML-DEVS models and the CML-DEVS compiler are publicly available, we believe the above results supports claim b) mentioned at the beginning of this section.

In Table I columns CML-DEVS, POWERDEVS and DEVS-SUITE show, respectively, the size in bytes of the CML-DEVS specification and the PowerDEVS and DEVS-Suite source code resulting from compiling the specification with the CML-DEVS compiler; finally, column TIME is the approximated compilation time (of both PowerDEVS and DEVS-Suite since differences are negligible). The compilation times shown in the table are approximate and rounded; they are measured from the command-line shell by simply taking the system time before and after compilation. The platform used for these tests is the following: AMD Athlon(tm) 7850 Dual-Core Processor CPU at 1.40GHz with 4 Gb of main memory, running Linux Ubuntu 14.04 (Trusty Tahr) of 64-bit with kernel 3.16.0-67-generic; the CML-DEVS compiler uses Java 1.7, ANTLR 4.5 and StringTemplate 4.0.8.

As the table shows, compilation times are acceptable given that by using the compiler engineers will get the concrete models from the mathematical description in a a few seconds. Note that programming these models would take much longer.

It is also clear that the sizes of the compiled models are higher than the CML-DEVS specifications. This is an indication of how CML-DEVS abstracts away syntactic details that otherwise need to be considered if the input languages of concrete simulators are used. The CML-DEVS compiler fills in these details for the engineer.

As another example of the code generated by the CML-DEVS compiler, Figure 13 lists the result of compiling the TrafficLights model shown in Figure 12 to the PowerDEVS input language (in the Appendix, Figure 14 lists the result of compiling the same model to DEVS-Suite). As Figure 13 shows, the code is clean, well-indented and structured, and strictly follows the conventions set forth by PowerDEVS (e.g., there is a function called dInt for the internal transition function, another function dExt for the external transition function and so on). Note the use of function findInSet which is a function implemented as part of the CML-DEVS framework. Functions such as this are included in library auxFunc which in turn is made available to the PowerDEVS model. PowerDEVS’ users would have to write their own set manipulation functions if they would have implemented the model without the CML-DEVS compiler. Instead, by using the compiler, they can simply write $s$ in \{RG,RY,GR\} and let the compiler to implement it. Last, but not least, compare the simplicity, familiarity and cleanliness of the CML-DEVS source code of Figure 12 with respect to the C++ code of Figure 13. For example, in the former there are no things such as casts and pointers (i.e. programming, not modeling, concepts), which are necessary in the latter. We argue that the model of Figure 12 can be written by an engineer completely unaware of C++, which is not the case for the program of Figure 13.

In our opinion, compilation times, the sizes of the CML-DEVS models and the corresponding PowerDEVS and DEVS-Suites concrete models and Figures 12 and 13, clearly support claims c) and d) mentioned above.

We believe that this evaluation shows that the whole approach (i.e. the CML-DEVS specification language and its multi-target compiler) is feasible and has several advantages over existing technology.

---

V. INTEGRATING CML-DEVS WITHIN EXISTING SIMULATORS

Mainstream DEVS simulators usually feature powerful GUIs that allow users to easily compose large models from existing ones. However, as we pointed out, atomic models have to be written in general-purpose programming languages. For this task, DEVS simulators either provide a programming editor or users can use the editor of their choice. Once the new atomic model is written it can be used as a component of larger models by a simple gesture of the GUI.

The CML-DEVS compiler can be integrated into the PowerDEVS and DEVS-Suite environments. If the appropriate code generators are developed (Section III-A), the compiler could in principle be integrated into DEVS-based systems such as DEVS-C++ [2], DEVSim++ [3], CD++ [4], JDEVS [6] and LSIS-DME [8]. Some of these systems are complex, powerful M&S environments. For example, PowerDEVS features a rich GUI interface and a large models library allowing users to easily compose models. As another example, JDEVS [6] integrates five modules: a simulation kernel, a GUI interface for coupled models, a models library, a connection to a GIS and a cellular simulation panel. The integration of M&S components into existing systems has a long tradition in the DEVS community.

Therefore, we propose to integrate the CML-DEVS compiler into existing DEVS simulators. In the first place, the corresponding code generator has to be implemented. Once the code generator is available the compiler can be integrated into the DEVS simulator system as follows:

1) Use the editor provided by your DEVS simulator to write CML-DEVS code for the new atomic models. Ideally, a CML-DEVS editor, such as a formula editor, can also be easily integrated.
2) Compile each CML-DEVS model into the input language of your simulator. Here the editor can call the CML-DEVS compiler.
3) Save the compiled model as any other atomic model of the simulator. CML-DEVS compiled models are indistinguishable from atomic models developed by other means.
4) Now users can couple compiled CML-DEVS models with other models as is normally done in your simulator (e.g. by using exactly the same GUI gesture).

In this way, simulators’ users will build their DEVS models as usual up until the moment they need to write a new atomic model. At this point the simulator environment can call the

```c
#include "HInt.h"

double HInt::ta() {
    return sigma;
}

void HInt::dint(double t) {
    X = X + sigma * dX;
    if (dX > 0) {
        sigma = dq / dX;
        q = q + dq;
    } else
    if (dX < 0) {
        sigma = -dq / dX;
        q = q - dq;
    } else
    sigma = inf;
}

void HInt::dext(Event x, double t) {
    xv = x.value;
    X = X + dX * e;
    if (xv > 0)
    sigma = (q + dq - X) / xv;
    else
    if (xv < 0)
    sigma = (q - epsilon - X) / xv;
    else
    sigma = inf;
    dX = xv;
}

Event HInt::lambda(double t) {
    if (dX == 0)
    y = q;
    else
    y = q + dq * dX / fabs(dX);
    return Event(&y, 0);
}

works that in a way or another are related to this approach.
CML-DEVS multi-target compiler regarding the automatic
generation of atomic DEVS models. However, there are some
features into larger models. Furthermore, if users want to try out
these atomic models on different simulators they can simply
take the CML-DEVS sources to the environment of the new
simulator (optionally the can compile the CML-DEVS models
and export the object code). From this point, coupling these
models proceeds as usual in the new simulator.

VI. RELATED WORK

As far as we know there is no approach such as the
CML-DEVS multi-target compiler regarding the automatic
generation of atomic DEVS models. However, there are some
works that in a way or another are related to this approach.
We will briefly comment on them in this section.

CML-DEVS has some relation with the standardization
effort carried on by the DEVS community [25]. One of
the standardization areas identified by this group is model
representation [26], [27], [28]. Notations such as CML-DEVS
could be used for model representation as they are independent
of simulators. DEVSpecL developed by Hong and Kim [29],
which somewhat inspired CML-DEVS, could also be used as
an abstract model representation. The relation between CML-
DEVS and DEVSpecL was commented by Hollmann et al.
elsewhere [9]. Mittal and Douglass [30] present a domain
specific language, based on Finite Deterministic DEVS, which,
with some limitations, can also be used to write abstract DEVS
models. These last two proposals would allow automatic
generation in order to get executable DEVS code in
different DEVS implementations, but apparently they do not
face this problem. Several works propose XML as a language
to describe DEVS models [31], [32], [28], [33]. One of
the reasons is that XML is platform independent and thus is some
times regarded as abstract. We believe that XML bears no
relation with the notion of abstract model as it is seen in the
CML-DEVS context (i.e. the conceptual distance with respect
to the language of mathematics and formal logic). XML could,
indeed, be useful to communicate and share models among
computers, systems and tools.

CML-DEVS is inspired by formal notations used in soft-
ware engineering such as Z [10], B [11] and TLA+ [12].
For example, the semantics of DEVS can be formalized in
TLA+ [34]. Engineering and scientific software tend to have
many errors that turn decision-making based on them risky
[35], [36], [37]. Researchers and engineers use software that
has not been formally or even extensively verified by experts
[38]. Some errors are introduced due to development processes
based on informal descriptions. In this sense, the CML-DEVS
approach is an attempt to formalize the process of developing
a concrete simulation model.

Model-Driven Engineering (MDE) and Model-Driven De-
velopment (MDD) attempt to translate abstract models into
more concrete models by means of model transformations.
Once the initial model and all the model transformations
are given, the final model can be automatically generated
[39]. CML-DEVS and its compiler can be seen in terms of
MDD: CML-DEVS would be the modeling language used
to describe an abstract model and the CML-DEVS compiler
would be a model transformation. On the other hand, the
DEVS community has attempted to adopt concepts and tech-
niques from MDE and MDD, in particular there are efforts in
defining model transformations [40], [41], [42], [43], [44],
[45], [46]. In these approaches, different modeling or meta-
modeling languages are proposed to describe DEVS models
in such a way that they can be automatically transformed by
the corresponding model transformations. None of these model-
ing languages describes atomic DEVS models using only
mathematical or logical concepts. The modeling and meta-
modeling languages proposed within the DEVS community,
instead, are based on general object-oriented technologies and
notations, notably UML, XML, OCL, etc. Although some of
the model transformations proposed in the works cited above
are automatic, some of them still require to write code in
some general-purpose programming language. In this way, we
think that our work provides a concrete implementation of a
modeling language and a model transformation, although not
inspired in MDE or MDD concepts.

VII. CONCLUDING REMARKS

We have presented the main features and properties of a
multi-target compiler for CML-DEVS specifications. We have
shown that CML-DEVS specifications are quite close to the

\begin{verbatim}
atomic HInt is (X, S, Y, dint, dext, lambda, ta, \end{verbatim}
\begin{verbatim} where
S is x S, dx, q, sigma : R end S
X is x X : R end X
Y is y : R end Y
dint is
x S = x S + sigma * dX
end dext
end ta
is sigma end ta
end atomic

Fig. 10. CML-DEVS source code for Cellier and Kofman's HInt
\end{verbatim}
atomic TrafficLights is \( \langle X, S, Y, \text{dint}, \text{dext}, \text{lamda}, \text{ta} \rangle \) where

\[
X \text{ is } \{M, A\} \text{ end } X \\
S \text{ is } s : \{RG, RY, GR, YR, BB\} \text{ end } S \\
Y \text{ is } \text{out} : \{\text{GREEN}, \text{YELLOW}, \text{BLINK}\} \text{ end } Y
\]

\[
\text{dint} \text{ is} \\
\text{defcases} \\
case s = RY \text{ if } s = RG \\
case s = GR \text{ if } s = RY \\
case s = YR \text{ if } s = GR \\
case s = RG \text{ if } s = YR \\
end \text{dint}
\]

\[
\text{dext} \text{ is} \\
\text{defcases} \\
case s = BB \text{ if } s \text{ in } \{RG, RY, GR, YR\} \land \text{value} = M \\
case s = RY \text{ if } s = BB \land \text{value} = A \\
end \text{dext}
\]

\[
\text{lamda} \text{ is} \\
\text{defcases} \\
case \text{out, GREEN} \text{ if } s \text{ in } \{RG, RY, GR\} \\
case \text{out, YELLOW} \text{ if } s = YR \\
case \text{out, BLINK} \text{ if } s = BB \\
end \text{lamda}
\]

\[
\text{ta} \text{ is} \\
\text{defcases} \\
case 60 \text{ if } s = RG \\
case 10 \text{ if } s \text{ in } \{RY, YR\} \\
case 50 \text{ if } s = GR \\
case \text{INF} \text{ if } s = BB \\
end \text{ta}
\]

Fig. 12. CML-DEVs source code for the traffic lights atomic model

```cpp
#include "TrafficLights.h"
using namespace auxFunc;

void TrafficLights::dint(double t) {
    TrafficLights prev("");
    if (prev.s == "RG") s = "RY";
    else if ((prev.s == "RY") s = "GR";
    else if (prev.s == "GR") s = "YR";
    else if (prev.s == "YR") s = "RG";
}

void TrafficLights::dext(Event x, double t) {
    TrafficLights prev("");
    std::string value = *(std::string*) (x.value);
    if (findInSet(prev.s, {"RY", "RG", "YR", "GR"}) \\
        && value == "M")
        s = "BB";
    else if (prev.s == "BB" && value == "A")
        s = "RY";
}

Event TrafficLights::lambda(double t) {
    if (findInSet(s, {"RY", "RG", "GR"})) {
        out = "GREEN";
        return Event(&out, Y_out);
    }
    else if (s == "YR") {
        out = "YELLOW";
        return Event(&out, Y_out);
    }
    else if (s == "BB") {
        out = "BLINK";
        return Event(&out, Y_out);
    }
    else return Event();
}

double TrafficLights::ta(double t) {
    if (s == "RG") return 60.0;
    else if (s == "RY") return 10.0;
    else if (s == "GR") return 50.0;
    else if (s == "YR") return 10.0;
    else if (s == "BB") return INFINITY;
}
```

Fig. 13. Result of compiling to PowerDEVS input language (C++) the traffic lights model of Figure 12

Fig. 11. Plot of the curves obtained by simulating the model given in Figure 8 (left) and Figure 9 (right)
way engineers would use mathematics to write their atomic DEVS models. Then we have shown that these specifications can be compiled into the input language of PowerDEVS and DEVS-Suite, which are mainstream DEVS simulators. We have also provided evidence that the code generation phase of the CML-DEVS compiler can be easily reimplemented as to generate code for other DEVS concrete simulators. Indeed, currently, code generators for PowerDEVS and DEVS-Suite are about 10% of the total compiler code, what makes evident that code generation is relatively easy. But it is even more important that plugging-in a new code generator is favored by the design of the compiler as it is based on well-known compiler designs. In fact, plugging-in a new code generator would require no code modification but only new code. A multi-target compiler would enable the possibility of easily simulating the same atomic model on an array of concrete simulators by simply recompiling the CML-DEVS specification.

Having an abstract, mathematics-oriented specification language for DEVS models and a compiler that automatically produces concrete models, would make the task of M&S much easier, productive and less error-prone. In effect, from the conception of the idea of a DEVS model to its implementation in the input language of major concrete simulators, either the engineer has to learn a programming language or to ask a programmer to implement his or her models. In either case, the initial model is read and interpreted by different persons along a lengthy time period. This multiple readings might introduce errors in the final model with respect to the initial, abstract model. Furthermore, if engineers want to see how the model behaves (in terms of performance, for instance) on different simulators, they need to implement it over and over again, in which case more errors can be introduced. Letting errors apart, the productivity would be increased if the same CML-DEVS specification can be automatically implemented for different simulators. Moreover, engineers would not need to learn to program nor to rest on a programmer to try out their models. Put it in another way, how much time and effort would an engineer need to learn C++ in such a way as to be able to produce the code of Figure 13? And conversely, how much time and effort would (s)he need to learn CML-DEVS, provided (s)he already knows DEVS, in such a way as to be able to produce the code of Figure 12? What is the core business of an electric engineer: to program or to write the CML-DEVS specification?

Having a multi-target compiler opens the door to, at least, two important aspects: a) the compiler can be optimized by experts in such a way as to produce the best possible code; and b) once the compiler is proved correct, model translation stops being a source of errors and problems.

### TABLE II

**BRIEF DESCRIPTION OF THE ATOMIC DEVS MODELS USED FOR THE EVALUATION OF THE CML-DEVS COMPILER**

<table>
<thead>
<tr>
<th>MODEL</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>ACCtrlUnit</td>
<td>These are three atomic models of an air conditioning system with cooling and heating units. The user can set the desired temperature while the system works as to maintain this temperature in the room [14].</td>
</tr>
<tr>
<td>ACTempProp</td>
<td>This is one atomic model part of a simple ATM machine. The ATM is only capable of dispensing money to a customer. ATMVerif verifies that the required amount is covered in balance [16].</td>
</tr>
<tr>
<td>CoolUnit</td>
<td>This models the movement of a billiard ball in a two dimensional pool table. The ball is struck by a cue (external event), it heads off in a direction at constant speed determined by the impulsive force imparted to it by the strike. Hitting the side of the table is considered as another input that sets the ball off going in a well-defined direction [13].</td>
</tr>
<tr>
<td>ATMVerif</td>
<td>In this model, the system outputs a “one” for every two “one”s that it receives. To do this it maintains a count of the “one”s it has received so far. When it receives a “one” that makes its count even, it goes into a transitory phase, “active”, to generate the output [13].</td>
</tr>
<tr>
<td>BilliardBall</td>
<td>This is the simplest of our models since it just outputs once a given constant and then remains idle forever [PowerDEVS model library].</td>
</tr>
<tr>
<td>ElevatorDoor</td>
<td>These two models are part of a coupled model describing an elevator in a one-elevator building. ElevatorDoor describes the behavior of the elevator’s door; and ElevatorEngine describes the behavior of its engine [17].</td>
</tr>
<tr>
<td>ElevatorEngine</td>
<td>These two models are part of a coupled model describing an elevator in a one-elevator building. ElevatorDoor describes the behavior of the elevator’s door; and ElevatorEngine describes the behavior of its engine [17].</td>
</tr>
<tr>
<td>Generator</td>
<td>Describes a simple proactive system. It has no inputs but when started in phase “active”, it generates outputs with a specific period [13].</td>
</tr>
<tr>
<td>HInt</td>
<td>Models an hysteretic quantized integrator which is used in continuous system simulation [18].</td>
</tr>
<tr>
<td>TrafficLights</td>
<td>This atomic model describes the behavior of two traffic lights in an intersection. These traffic lights have two modes of operation: autonomous, in which the lights behave as expected; and manual, in which the lights blink yellow. There is some external mechanism that switches between modes by sending two events [15].</td>
</tr>
<tr>
<td>Server</td>
<td>This model describes a simple processing server. The server receives jobs to be executed during a user-defined period of time. The server keeps a queue of pending jobs [19].</td>
</tr>
<tr>
<td>Switch</td>
<td>A switch is modeled as a system with pairs of input and output ports. When the switch is in the standard position, jobs arriving on port “in” are sent out on port “out”, and similarly for ports “in1” and “out1”. When the switch is in its other setting, the input-to-output links are reversed [13].</td>
</tr>
</tbody>
</table>
